In this chemical equation, a new product is formed by combining two to three combinations of reactants. For instance,  $H_2 + O_2 \rightarrow H_2O$ . This is a chemical equation where two atoms of hydrogen are combined to form a product, water. This is why this reaction is called as synthesis reaction.

A chemical reaction represents a change in the distribution of atoms, but not in the number of atoms. In this reaction, and in most chemical reactions, bonds are broken in the reactants (here, Cr-O and N-H bonds), and new bonds are formed to create the products (here, O-H and N≡N bonds).

A chemical reaction is a process in which one or more substances, also called reactants, are converted to one or more different substances, known as products. Substances are either chemical elements or compounds. A chemical reaction rearranges the constituent atoms of the reactants to create different substances as products. The properties of the products are different from those of the reactants.

### **chemical reaction | Definition, Equations, Examples ...**

Chemical reactions tend to involve the motion of electrons, leading to the formation and breaking of chemical bonds. There are several different types of chemical reactions and more than one way of classifying them. Oxidation-Reduction or Redox Reaction In a redox reaction, the oxidation numbers of atoms are changed.

### **Types of Chemical Reactions (With Examples)**

When a chemical reaction occurs, the original substances put together, called reactants, lose their chemical properties and become different substances called products with a different set of chemical properties. Reactions where energy is released are called exothermic reactions. When energy is absorbed, it is called an endothermic reaction.
