In mathematics, the Bott periodicity theorem describes a periodicity in the homotopy groups of classical groups, discovered by Raoul Bott, which proved to be of foundational significance for much further research, in particular in K-theory of stable complex vector bundles, as well as the stable homotopy groups of spheres. Bott periodicity can be formulated in numerous ways, with the periodicity in question always appearing as a period-2 phenomenon, with respect to dimension, for the theory assoc

Bott's periodicity theorem establishes the property of the stable homotopy type of the unitary group U , consisting in the fact that $\{\Omega^2\} U \sim U$, where ΩX is the space of loops on X , and \sim is weak homotopy equivalence, in particular $\pi_i(U) = \pi_{i+2}(U)$ for $i = 0, 1, \dots$ where π_i is the i -th homotopy group.

Periodicity Theorem, Part I: For each n , V_n is a thick subcategory of $FH(p)$ and we have $F_{p;n+1} \vee V_n = F_{p;n}$. Combining this with the Thick Subcategory Theorem tells us that either $V_n = F_{p;n}$ or $V_n = F_{p;n+1}$. To prove the periodicity theorem, it remains to rule out the second case. It is enough to find one spectrum that is in $F_{p;n}$ but not in $F_{p;n+1}$ (in other words, a

Introduction The periodicity theorem for the infinite unitary group can be interpreted as a statement about complex vector bundles. As such it describes the relation between vector bundles over X and $X \times \mathbb{C}P^2$, where X is a compact (1) space and $\mathbb{C}P^2$ is the 2-sphere.

Theorem 4 (Periodicity Theorem). Let X be a finite p -local spectrum of type n . Then X admits a v_n -self map. It will be useful to reformulate the notion of a v_n -self map. If X is a finite p -local spectrum, then $R = \pi_* DX$ has the structure of a ring spectrum. Moreover, giving a self map $kX \rightarrow X$ is equivalent to giving an element of $\pi_* kR$. The condition of being a v_n

Main Theorem The Arf-Kervaire elements $j \in \pi_{2j+1}(S^0)$ do not exist for $j \neq 0$. Our strategy is to find a map $S^0 \rightarrow \Sigma$ to a nonconnective spectrum with the following properties. (i) It has an Adams-Novikov spectral sequence in which the image of each j is nontrivial. This is the Detection Theorem discussed by Hopkins yesterday. (ii) $\pi_{-2}(\Sigma) = 0$.

Equation 2204d means that $u_{nk}(r)$ has the same periodicity as the Hamiltonian \hat{H} for any lattice vector R of the Hamiltonian. An alternative formulation of Bloch's theorem is that the eigenstates of a periodic Hamiltonian \hat{H} can be chosen so that for any lattice vector R of the Hamiltonian, associated with each ψ is a wave vector k and thus ...

Logarithmic bounds for Roth's theorem via almost-periodicity, Discrete Analysis 2019:4, 20pp. A central result of additive combinatorics, Roth's theorem, asserts that for every $\delta > 0$ there exists N such that every subset of $\{1, 2, \dots, N\}$ of size at least δN contains an arithmetic progression of length 3. This is the first non-trivial case of Szemerédi's theorem, proved over 20 years later, which is the corresponding statement for progressions of general length.

The Bott periodicity theorem is of fundamental importance in many areas of mathematics, from algebraic topology to functional analysis. It appears unexpectedly in different guises and I would like to explain some of these as well as the influence it has had on the development of different fields. I will concentrate on two roles that periodicity plays.

Namely, the periodicity theorem states that: Theorem 4 There is an eight-dimensional bundle over $C P^\infty$, whose Stiefel-Whitney class is nonzero, such that multiplication by it determines an isomorphism for any CW complex. Recall that our goal is to show that the Stiefel-Whitney classes of any vector bundle over a nine-fold suspension vanish.
