Embankment Dam Engineering

Embankment dams come in two principal varieties, earthfill embankment dams and rockfill embankment dams. An earthfill embankment dam is made by building a foundation wall which is embedded into the rock below the dam to prevent water flowing beneath it and then creating a core of impermeable

Construction of embankment dams has an economical advantage; i.e., the dam project can be planned in the outskirts of city area because of the merit mentioned above, and construction materials are principally to be supplied near the dam site.

Design and Construction of Embankment Dams

Embankment dams are mainly made from natural materials. They are suited to sites with wide valleys and shallow slopes, creating relatively wide and shallow reservoirs. They can be constructed on relatively weaker and not homogenous soils.

An embankment dam is a large artificial dam. It is typically created by the placement and compaction of a complex semi- plastic mound of various compositions of soil, sand, clay, or rock. It has a semi-pervious waterproof natural covering for its surface and a dense, impervious core. This makes such a dam impervious to surface or seepage
